# Rope - Data Structure Exercises

Nicholas Elliot

## Weight

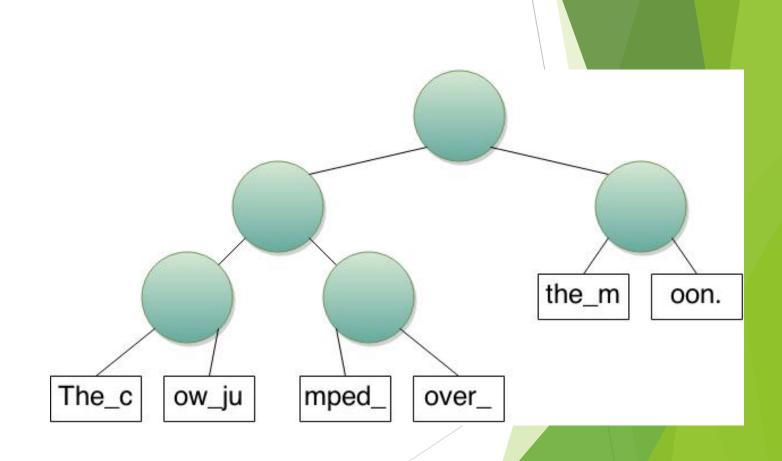

- Each node has a weight value equal to the length of its string plus the sum of all leaf nodes' weight in its left subtree.
- YOU: Label each node with its weight

### Index

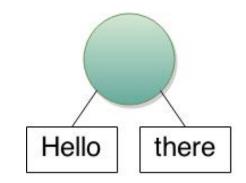

Here is code for index:

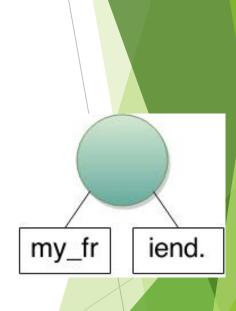

YOU: Trace the rope to find index(root, 12)

#### Concat

- Concat(S1, S2): concatenate two ropes, S1 and S2, into a single rope.
- A concatenation can be performed simply by creating a new root node with  $left = S_1$  and  $right = S_2$ ,
- ► YOU: Concat these two separate ropes into a single rope.

## Split

- Split (i): split the rope into two new strings S1 and S2
- There are two cases that must be dealt with:
  - The split point is at the end of a string (i.e. after the last character of a leaf node)
  - 2. The split point is in the middle of a string.
- YOU: Perform split(14)
  - Redraw the rope to compensate for the case 2.
  - ► Then, draw a line through the rope, across the branches to be removed.
